

**TITLE:** Periodic Dental Examinations for Oral Health: A Review of Clinical Effectiveness, Cost Effectiveness, and Guidelines

**DATE:** 21 May 2014

## **CONTEXT AND POLICY ISSUES**

While there is no accepted universal definition, a routine dental examination generally involves the assessment of the teeth, gingiva, the bones and temporomandibular joint of the face, and mucous membranes within the mouth and throat by a dentist.<sup>1,2</sup> The purpose of a dental examination is multifactorial: the exam is designed to identify problems with the teeth, including decayed, damaged, or missing teeth, positioning of the teeth, and ensuring that there are no problems with previous dental work such as crowns or fillings.<sup>2</sup> In addition, the gingiva is evaluated for signs of periodontal disease including periodontal pockets and bleeding, and the mucous membranes in the mouth and throat are examined for signs of oral cancer.<sup>2</sup> Lastly, bones of the face and jaw and the biomechanics of the temporomandibular joint may be examined.<sup>3</sup> If problems are identified during the dental exam, the dentist can then develop an appropriate treatment plan.<sup>2</sup>

Dental problems can lead to significant patient morbidity and in some cases, mortality due to oral cancer.<sup>4</sup> While dental examinations are needed to identify and manage oral diseases and dental issues, there is debate about the ideal frequency of dental examination recalls; that is, how often a person should undergo a dental examination.<sup>1</sup> Given resource demands, the costs associated with dental care, and the fact that approximately 32% of Canadians do not have dental insurance, there must be a balance between the costs associated with dental care and the effectiveness of the dental examination for identification and management of dental conditions based on the progression of dental disease.<sup>4-6</sup>

The purpose of this Rapid Response report is to evaluate the clinical and cost effectiveness evidence for annual dental exams relative to other intervals, and to report the recommendations of clinical practice guidelines discussing the frequency of dental examinations. This report supplements a previous CADTH report evaluating the recommended frequency for dental scaling and polishing.<sup>7</sup>

*Disclaimer:* The Rapid Response Service is an information service for those involved in planning and providing health care in Canada. Rapid responses are based on a limited literature search and are not comprehensive, systematic reviews. The intent is to provide a list of sources and a summary of the best evidence on the topic that CADTH could identify using all reasonable efforts within the time allowed. Rapid responses should be considered along with other types of information and health care considerations. The information included in this response is not intended to replace professional medical advice, nor should it be construed as a recommendation for or against the use of a particular health technology. Readers are also cautioned that a lack of good quality evidence does not necessarily mean a lack of effectiveness particularly in the case of new and emerging health technologies, for which little information can be found, but which may in future prove to be effective. While CADTH has taken care in the preparation of the report to ensure that its contents are accurate, complete and up to date, CADTH does not make any guarantee to that effect. CADTH is not liable for any loss or damages resulting from use of the information in the report.

*Copyright:* This report contains CADTH copyright material. It may be copied and used for non-commercial purposes, provided that attribution is given to CADTH.

*Links:* This report may contain links to other information available on the websites of third parties on the Internet. CADTH does not have control over the content of such sites. Use of third party sites is governed by the owners' own terms and conditions.

## RESEARCH QUESTIONS

1. What is the comparative clinical evidence for dental examinations every 12 months compared with other intervals for the prevention of oral disease?
2. What is the cost-effectiveness of dental examinations every 12 months compared with other intervals for the prevention of oral disease?
3. What are the evidence-based guidelines regarding the frequency of routine dental examinations for prevention of oral disease?

## KEY FINDINGS

Evidence suggests that annual or more frequent recall may result in increased tooth retention, but the ideal interval for routine dental examination is unclear. No evidence was identified examining cost-effectiveness. Younger individuals appear to benefit from annual dental exams, whereas those aged 60 years and older did not appear to benefit from annual dental exams in terms of presence of periodontal disease, but annual exams did increase the likelihood for having > 20 teeth. Those at high risk for periodontal disease may benefit from more frequent dental exams (two per year) compared to those at low risk for periodontal disease.

## METHODS

### Literature Search Strategy

A limited literature search was conducted on key resources including PubMed, The Cochrane Library (2014, Issue 3), University of York Centre for Reviews and Dissemination (CRD) databases, Canadian and major international health technology agencies, as well as a focused Internet search. No filters were applied to limit the retrieval by study type. The search was limited to English language documents published between Jan 1, 2009 and Apr 23, 2014.

### Selection Criteria and Methods

One reviewer screened the titles and abstracts of the retrieved publications for relevancy, and evaluated the relevant full-text publications for the final article selection based on the criteria listed in Table 1.

**Table 1: Selection Criteria**

<b>Population</b>	Adults (age 18 to 65)
<b>Intervention</b>	Routine dental examination every 12 months
<b>Comparator</b>	Dental examinations at different intervals (e.g. 6, 18, 24 months or no examination)
<b>Outcomes</b>	Question 1: Oral health outcomes (e.g., caries, early detection of oral cancer, periodontal disease) Question 2: Cost effectiveness Question 3: Clinical practice guidelines recommendations
<b>Study Designs</b>	Question 1: Health technology assessments, meta-analyses, systematic reviews, randomized controlled trials, non-randomized

studies

Question 2: Health technology assessments, economic evaluations

Question 3: Clinical practice guidelines

**Exclusion Criteria**

Studies were excluded if they did not meet the selection criteria, if they were duplicate publications, or were published prior to January 1, 2009.

**Critical Appraisal of Individual Studies**

The Downs and Black checklist was used to critically appraise the observational studies included in this report.<sup>8</sup> Summary scores were not calculated for the included studies, rather, a review of the strengths and limitations of each included study were described.

**SUMMARY OF EVIDENCE****Quantity of Research Available**

The literature search identified 483 citations, with an additional five citations identified from the grey literature. After screening of the abstracts, 22 potentially relevant studies were identified for full-text review. After full text review, a total of 3 studies were included in this review.

Three observational studies met the inclusion criteria. There were no economic analyses or clinical practice guidelines identified in the literature search.

Appendix 1 lists additional resources not included in this report, including a clinical practice guideline from 2004, and an ongoing randomized trial evaluating the relationship between varying dental exam intervals and dental outcomes (expected completion 2019).

The PRISMA flowchart provides the details of the study selection process (Appendix 2).

**Summary of Study Characteristics**

Details on study design, critical appraisal, and study findings are located in Appendices 3, 4, and 5, respectively.

*Study Design*

Among the three studies included in this review, all were observational studies.<sup>9-11</sup> The observational studies included a prospective cohort study,<sup>10</sup> a retrospective cohort study,<sup>11</sup> and a cross-sectional study.<sup>9</sup>

*Country of Origin*

One of the included studies was from the United States.<sup>11</sup> one study was from Sweden<sup>9</sup> and one from New Zealand.<sup>10</sup>

### *Patient Population*

The patient populations varied across the studies. The study from Sweden included individuals from the Swedish National Study on Aging and Care, and participants ranged in age from 60 to 96 years old.<sup>9</sup> Giannobile and colleagues used the Delta Dental of Michigan dental insurance claims database (requiring >15 years of claims data for inclusion) to identify their study population, and the mean age of participants in this study was 47 years.<sup>11</sup> Thomson and colleagues included people from the Dunedin Multidisciplinary Health and Development Study conducted in New Zealand.<sup>10</sup> The Dunedin study recruited individuals at 15 years of age, and assessed them at 18 years, 26 years, and 32 years.<sup>10</sup>

### *Interventions and Comparators*

For the included cohort studies, the intervention was an annual dental examination, and the comparator for the retrospective cohort was two visits per year.<sup>10,11</sup> The prospective cohort categorized the comparator group as non-routine attenders based on those who did not meet the criteria for routine attenders. Non-routine attenders were defined as those who did not regularly see a dentist for an exam, and did not have a dental visit in the previous 12 months.<sup>10</sup> In terms of the cross-sectional study, an annual dental exam was compared with two or more visits per year and less than one dental exam per year to identify the possibility of an association between dental exam frequency and dental outcomes.<sup>9</sup>

### *Clinical Outcomes*

All of the studies examined health outcomes associated with varying dental recall exam intervals.<sup>9-11</sup> All three of the included studies evaluated tooth loss or total number of teeth.<sup>9-11</sup> In addition to total number of teeth, Renvert and colleagues examined alveolar bone loss, periapical lesions, and number of endodontically treated teeth.<sup>9</sup> Thomson and colleagues evaluated self-rated oral health, mean number of decayed, missing, or filled tooth surfaces (DMFS), and mean number of decayed surfaces (DS) in addition to missing teeth.<sup>10</sup>

## **Summary of Critical Appraisal**

All three of the included studies were observational studies, and as a result, study participants were not randomized to dental exam recall interval.<sup>9-11</sup> Based on the lack of randomization, and the fact that two of the studies did not report whether they adjusted for potential confounding variables, such as brushing frequency or other home oral health care, in their statistical analysis,<sup>9,11</sup> the results of each study must be interpreted with caution due to the possibility of confounding. All studies clearly indicated their aim, objectives, and/or study hypotheses, and all of the studies clearly reported the methods for identifying the study outcomes.<sup>9-11</sup> None of the studies reported a sample size or power calculation, so for studies that did not detect a statistically significant difference between the intervention and control groups,<sup>9-11</sup> it is unclear whether the studies were not of adequate size to detect a difference, or whether a statistical difference truly does not exist between groups.

## **Summary of Findings**

*What is the comparative clinical evidence for dental examinations every 12 months compared with other intervals for the prevention of oral disease?*

Giannobile and colleagues identified patients free of periodontal disease from the Delta Dental of Michigan dental insurance claims database.<sup>11</sup> They stratified study participants into two groups: high risk for periodontal disease, defined as the presence of at least one of three risk factors including current or recent smoking, a diagnosis of diabetes, or those with a positive interleukin-1 genotype buccal swab; those stratified into the low risk for periodontal disease did not have any of the risk factors present.<sup>11</sup> The study authors found that, for the outcome of tooth loss, low risk patients who had one preventive visit per year (event rate: 16.4/100 patients) did not have a significantly different event rate compared to low risk patients with two preventive visits per year (event rate: 13.8/100 patients) ( $P = 0.092$ ).<sup>11</sup> However, for patients at high risk for periodontal disease, those who had two preventive visits per year were significantly less likely to have tooth loss (event rate: 16.9/100 patients) compared to those who had one preventive visit per year (event rate: 22.1/100 patients) ( $P = 0.002$ ).<sup>11</sup> These results suggest that those at high risk for periodontal disease may benefit from dental exams every six months compared to every twelve months.

Renvert and colleagues examined patients from the Swedish National Study on Aging and Care – Blekinge, and the ages in this study ranged from 60 to 96 years old.<sup>9</sup> Study participants were divided into three groups: those who underwent an annual dental exam, those who underwent a dental exam twice yearly or more, and those who underwent a dental exam less than once yearly.<sup>9</sup> Among those 60 and 66 years of age, 73% of people who had an annual dental exam had > 20 teeth compared with 37% with > 20 teeth of those who went to the dentist infrequently, however, statistical testing was not reported for this outcome.<sup>9</sup> Among patients > 81 years old, 1.8% of patients with infrequent dental visits had > 20 teeth, while 37% of patients who had dental visits more than once yearly had > 20 teeth. The authors then completed statistical modeling to evaluate alveolar bone loss, periapical lesions, and the number of endodontically treated teeth while adjusting for age and number of missing teeth and found no statistically significant difference for these outcomes based on frequency of dental exams.<sup>9</sup>

Lastly, Thomson and colleagues evaluated a group of patients registered in the Dunedin at ages 18, 26, and 32 years.<sup>10</sup> They consistently found that, in those who were regular attenders for dental examinations (that is, those that had at least one dental exam per year), self-reported oral health was higher ( $P < 0.05$  for all ages).<sup>10</sup> In addition, regular attenders were less likely to have tooth loss due to caries, had a reduced mean number of decayed surfaces, and a reduced mean number of decayed, missing, or filled tooth surfaces compared with those who did not annually have a dental exam ( $P < 0.05$  for all comparisons and all ages).<sup>10</sup> The authors also noted that the difference in the measured outcomes was greater with longer exposure to attendance, with long-term routine attenders having the best oral health by age 32.<sup>10</sup>

## Limitations

The conclusions of this report are limited by the observational nature of the studies included. In addition, none of the studies were completed in Canada, and as a result, it is unclear whether important differences exist in terms of the components of a dental examination between countries. Also, the comparisons in the included studies were limited by the dental exam interval time frames, as it would have been useful to have 18 month and 24 month comparisons in a wider variety of populations. It is clear that randomized controlled trials are needed in different populations, including those in good health and those with risk factors for periodontal disease, to identify the appropriate dental examination recall period. In addition, cost-effectiveness studies are needed to assess the economic implications of different dental examination intervals.

## CONCLUSIONS AND IMPLICATIONS FOR DECISION OR POLICY MAKING

Based on the studies included in this review, it appears that it may be beneficial to individualize the dental examination interval based on the patient's age and risk for periodontal disease. Evidence suggests that annual or more frequent recall may result in increased tooth retention, but the ideal interval for routine dental examination is unclear. Younger individuals appear to benefit from annual dental exams, whereas those aged 60 years and older did not appear to benefit from annual dental exams in terms of likelihood for periodontal disease, but did benefit in terms of number of teeth. Those at high risk for periodontal disease may benefit from more frequent dental exams (two per year) compared to those at low risk for periodontal disease. No cost-effectiveness evidence or evidence-based guidelines were identified.
