

Pneumococcal Vaccines

Revised: October 31, 2018.

Drug Levels and Effects

Summary of Use during Lactation

The Centers for Disease Control and Prevention and several health professional organizations state that vaccines given to a nursing mother do not affect the safety of breastfeeding for mothers or infants and that breastfeeding is not a contraindication to pneumococcal vaccine. Immunization of the mother during the third trimester of pregnancy markedly increases the amount of pneumococcal antibodies in breastmilk.[1] Breastfed infants should be vaccinated according to the routine recommended schedules.[2][3][4]

Drug Levels

Maternal Levels. Relevant published information was not found as of the revision date.

Infant Levels. Relevant published information was not found as of the revision date.

Effects in Breastfed Infants

Limited data indicate that breastfeeding can enhance the response of the infant to certain vaccine antigens.[2][4][5][6]

Immunization of pregnant women with pneumococcal vaccine increased the specific secretory IgA content of milk and colostrum.[7][8][9][10][11][12] These antibodies in colostrum help inhibit epithelial adhesion of pneumococci to pharyngeal epithelial cells.[12] Some evidence of decreased pneumococcal disease has been found among breastfed infants of vaccinated mothers.[10] Infants breastfed for longer than 90 days have a better antibody response to some pneumococcal strains in the vaccine at 13 months of age than those breastfed less than 90 days.[13]

Effects on Lactation and Breastmilk

Relevant published information was not found as of the revision date.
